March 12, 2026

Abstract

This analysis note details the extraction of absolute double-differential Drell-Yan cross sections for pp and pd interactions using data collected with the Roadset 67 trigger. We present these findings for preliminary collaboration approval ahead of upcoming conference presentations. This study advances prior analyses by integrating both Liquid Hydrogen (LH_2) and Liquid Deuterium (LD_2) target datasets, alongside implementing significant methodological upgrades to the efficiency correction framework. To mitigate statistical limitations, the reconstruction efficiency is now derived from a global, high-statistics parameterization of the Drift Chamber 1 ($D1$) occupancy, integrated across all kinematic bins (DocDB 11427¹). Furthermore, the hodoscope efficiency correction has transitioned from a global constant to a rigorous, event-by-event calculation utilizing dimuon track kinematics and paddle-specific response mappings (DocDB 11467²). We report the final double-differential Drell-Yan cross-sections, $d^2\sigma/dx_F dM$, and provide comparisons with Next-to-Leading-Order (NLO) Quantum Chromodynamics (QCD) predictions.

1 Introduction

In October 2025, a preliminary evaluation of the pp Drell-Yan absolute cross section utilizing a 120 GeV proton beam was documented in DocDB 11383³. The present analysis standardizes the extraction framework for both pp and pd datasets, a necessary harmonization given that the pp cross section is requisite for correcting the hydrogen contamination within the liquid deuterium target. To ensure a robust extraction of the physics observables, this analysis incorporates several critical algorithmic and statistical improvements implemented since the preliminary report:

- **Global Reconstruction Efficiency Parameterization:** Prior methodologies parameterized reconstruction efficiency as a function of Station-2 occupancy ($D2$), utilizing distinct curves for each kinematic bin. This approach yielded kinematically segregated samples with poor statistical power and consequently large uncertainties. As established in DocDB 11427⁴, the reconstruction efficiency exhibits negligible kinematic dependence. Consequently, we now employ a unified, high-statistics efficiency curve parameterized against Station-1 occupancy ($D1$). This shift to $D1$ also eliminates combinatorial ambiguities when computing efficiencies for mixed events.
- **Dimuon-Level Hodoscope Efficiencies:** Earlier studies applied a global hodoscope and trigger efficiency correction (DocDB 10809⁵) inherently optimized for J/ψ production. To accurately reflect the Drell-Yan continuum, we have adopted an event-by-event calculation. Utilizing paddle-specific efficiencies derived from single-track data (DocDB 11467⁶), the hodoscope efficiency is now computed for each kinematic bin based directly on the constituent tracks of the accepted dimuon pairs.
- **Mixed Event Contamination Correction:** Previously, the reconstruction efficiency correction relied exclusively on the yield of dimuon events in the physical data, neglecting the differing occupancy profiles of mixed events. Because the $D1$ distribution of mixed events diverges from that of regular events, the combinatorial background inherently skewed the efficiency correction. We have addressed this systematic bias by employing a discrete contamination correction method detailed in DocDB 11448⁷.

2 Analysis Methodology

The determination of the absolute Drell-Yan cross-section demands a multi-stage process: rigorous selection of dimuon candidates, quantitative background subtraction, precise normalization via integrated luminosity, and detailed correction for geometric acceptance and detector inefficiencies.

2.1 Data and Monte Carlo Samples

This analysis is predicated upon the “Roadset 67” trigger configuration dataset recorded by the SeaQuest spectrometer. The primary physical data arrays for the Liquid Hydrogen (LH_2) target, Liquid Deuterium (LD_2) target, and the requisite empty flask configurations are centralized at:

`/sequest/users/apun/e906_projects/rs67_merged_files/`

- **LH_2 Target Data:** `merged_RS67_3089LH2.root`

³<https://sequest-docdb.fnal.gov/cgi-bin/sso/ShowDocument?docid=11383>

⁴<https://sequest-docdb.fnal.gov/cgi-bin/sso/ShowDocument?docid=11427>

⁵<https://sequest-docdb.fnal.gov/cgi-bin/sso/ShowDocument?docid=10809>

⁶<https://sequest-docdb.fnal.gov/cgi-bin/sso/ShowDocument?docid=11467>

⁷<https://sequest-docdb.fnal.gov/cgi-bin/sso/ShowDocument?docid=11448>

417 • **LD₂ Target Data:** merged_RS67_3089LD2.root

418 • **Empty Flask Data:** merged_RS67_3089Flask.root

419 To facilitate event-level detector performance corrections, the base ROOT files were aug-
420 mented with variables explicitly tracking the reconstruction efficiency (`recoeff`), the hodoscope
421 efficiency (`hodocoeff`), and their respective propagated uncertainties (`recoeff_error`, `hodocoeff_error`).
422 The updated ntuples are archived at:

423 • /sequest/users/ckuruppu/rootfiles/rs67/merged_RS67_3089_LH2_recoeff_hodocoeff.root

424 • /sequest/users/ckuruppu/rootfiles/rs67/merged_RS67_3089_LD2_recoeff_hodocoeff.root

425 • /sequest/users/ckuruppu/rootfiles/rs67/merged_RS67_3089_Flask_recoeff_hodocoeff.root

426 The inclusion of empty flask data is critical for isolating target-specific interactions by sub-
427 tracting invariant background generated by the beam interacting with the containment vessel
428 and upstream materials.

429 Extensive Geant4-based Monte Carlo (MC) simulations were deployed to map the geomet-
430 ric acceptance and reconstruction efficiencies of the spectrometer. The simulated events were
431 propagated through the complete SeaQuest detector geometry and reconstruction chain:

432 • **Acceptance Studies:** Drell-Yan topologies were generated across a 4π solid angle (“thrown”)
433 and filtered through the standard event selection protocol (“accepted”). The baseline files
434 are located in /sequest/users/chleung/pT_ReWeight/, including the *_M027_S001_*
435 series for both LH₂ and LD₂ geometries.

436 • **Efficiency Studies:** To quantify the impact of intense ambient hit multiplicities on track
437 finding, identical kinematic sets were processed both organically (“clean”) and with an
438 overlay of random experimental background hits (“messy”).

439 Crucially, all simulated events are intrinsically weighted to emulate the transverse momentum
440 (p_T) spectrum mapped in the physical data.

441 2.2 Event Selection

442 A stringent, multi-tiered selection protocol is applied to isolate statistically pure Drell-Yan events
443 from the underlying continuum of beam-dump interactions, muon combinatorics, and cosmic
444 background.

445 • **Data Quality:** Only spills explicitly validated by the standard SeaQuest offline qual-
446 ity monitoring are retained. An explicit trigger requirement (`MATRIX1 == 1`) enforces
447 top/bottom spectrometer coincidence.

448 • **Track and Vertex Quality:** We mandate the standard collaboration “Chuck Cuts”
449 (DocDB 2111⁸) to ensure robust spatial reconstruction. This protocol mandates thresholds
450 on track χ^2 , hit multiplicity, target-vs-dump vertex probability, and magnet aperture
451 fiducial cuts. The specific boundary conditions are tabulated in tables 1 to 3 of section 10.

452 • **Kinematic Boundaries:** To isolate the Drell-Yan continuum and suppress charmonium
453 resonant states (J/ψ , ψ'), a lower mass bound of $M_{\mu\mu} > 4.2$ GeV/ c^2 is strictly enforced,
454 alongside an integration window of $0 < x_F < 0.8$.

455 Following this filtering cascade, the primary and mixed-event dimuon yields for all target
456 configurations are isolated into their respective mass and x_F bins, as illustrated in fig. 1.

⁸<https://sequest-docdb.fnal.gov/cgi-bin/ss0/ShowDocument?docid=2111>

Figure 1: Dimuon distributions after applying event selection criteria.

2.3 Cross-Section Formalism

The extraction of the double-differential pp cross-section within a localized kinematic space $(\Delta M, \Delta x_F)$ follows the formalism outlined in DocDB 11445⁹:

$$\frac{d^2\sigma_{pp}}{dM dx_F} = \frac{1}{\epsilon_{\text{acc}} \mathcal{L} \Delta M \Delta x_F} \left[\frac{Y_{\text{total}}^{\text{LH2}} - Y_{\text{mixed}}^{\text{LH2}}}{\langle \epsilon_{\text{signal}}^{\text{LH2}} \rangle} - \frac{I_{\text{LH2}}}{I_{\text{flask}}} \left(\frac{Y_{\text{total}}^{\text{flask}} - Y_{\text{mixed}}^{\text{flask}}}{\langle \epsilon_{\text{signal}}^{\text{flask}} \rangle} \right) \right] \quad (1)$$

⁹<https://sequester-docdb.fnal.gov/cgi-bin/sso/ShowDocument?docid=11445>

where Y_{total} and Y_{mixed} denote the prompt and combinatorial background yields respectively, and I represents the integrated proton flux (POT) incident on a given target. The true signal efficiency, $\langle\epsilon_{\text{signal}}\rangle$, separates the detector response of real correlated pairs from that of mixed tracks:

$$\langle\epsilon_{\text{signal}}\rangle = \frac{1}{Y_{\text{total}} - Y_{\text{mixed}}} [\langle\epsilon_{\text{total}}\rangle Y_{\text{total}} - \langle\epsilon_{\text{mixed}}\rangle Y_{\text{mixed}}] \quad (2)$$

Here, $\langle\epsilon_{\text{total}}\rangle$ and $\langle\epsilon_{\text{mixed}}\rangle$ map the composite event efficiencies (DocDB 11448¹⁰). For an individual accepted dimuon candidate i , the overarching efficiency is the product of the discrete reconstruction and hodoscope survival probabilities:

$$\epsilon^i = \epsilon_{\text{reco}}^i \cdot \epsilon_{\text{hodo}}^i \quad (3)$$

The macroscopic integrated luminosity $\mathcal{L}$ governs the absolute normalization:

$$\mathcal{L} = N_{\text{incident}} \cdot \frac{N_A \rho L}{A} \cdot f_{\text{atten}} \quad (4)$$

where N_A is Avogadro's constant, A is the target molar mass, and f_{atten} defines the hadronic beam attenuation coefficient. For the 50.8 cm LH₂ flask ($\rho_H = 0.0708$ g/cm³), the target areal density is 3.5966 g/cm² with an associated $f_{\text{atten}} = 0.966$ (DocDB 8588¹¹). The acceptance parameter ϵ_{acc} is derived purely from Monte Carlo mapping.

Extraction of the pd cross section necessitates a subsequent correction for the intrinsic proton (hydrogen) contamination present in the deuterium cryogen:

$$\begin{aligned} \frac{d^2\sigma_{pd}}{dM dx_F} = & \frac{1}{\epsilon_{\text{acc}} \mathcal{L} \Delta M \Delta x_F} \left(\left[\frac{Y_{\text{total}}^{\text{LD2}} - Y_{\text{mixed}}^{\text{LD2}}}{\langle\epsilon_{\text{signal}}^{\text{LD2}}\rangle} - \frac{I_{\text{LD2}}}{I_{\text{flask}}} \left(\frac{Y_{\text{total}}^{\text{flask}} - Y_{\text{mixed}}^{\text{flask}}}{\langle\epsilon_{\text{signal}}^{\text{flask}}\rangle} \right) \right] \right. \\ & \left. - \frac{T_{HD}}{T_{HH}} \frac{I_{\text{LD2}}}{I_{\text{LH2}}} \left[\frac{Y_{\text{total}}^{\text{LH2}} - Y_{\text{mixed}}^{\text{LH2}}}{\langle\epsilon_{\text{signal}}^{\text{LH2}}\rangle} - \frac{I_{\text{LH2}}}{I_{\text{flask}}} \left(\frac{Y_{\text{total}}^{\text{flask}} - Y_{\text{mixed}}^{\text{flask}}}{\langle\epsilon_{\text{signal}}^{\text{flask}}\rangle} \right) \right] \right) \end{aligned} \quad (5)$$

We apply the previously measured fractional target thicknesses $T_{HD} = 0.1084$ and $T_{HH} = 3.5966$ (DocDB 11227¹²), where T_{HD} is explicitly POT-weighted across the varying purity regimes of the LD₂ run periods.

3 Acceptance Correction

The forward topology of the SeaQuest spectrometer necessitates a rigorous unfolding of its geometric acceptance. The survival probability of a generated Drell-Yan pair is highly dependent on invariant mass (M) and longitudinal momentum fraction (x_F). The binned acceptance fraction is analytically defined via MC as:

$$\text{Acceptance (A)} = \frac{N_{\text{accepted}}}{N_{\text{thrown}}} \quad (6)$$

where N_{accepted} reflects the yield traversing the digital simulated geometry (`*clean_occ_pTxFweight*`) and N_{thrown} denotes the phase space baseline in 4π (`*4pi_pTxFweight*`). To preserve resolution, the array is partitioned into 16 x_F domains (width $\Delta x_F = 0.05$ up to 0.8) and 11 distinct mass bins mapping the high-mass continuum ($4.2 \leq M < 8.7$ GeV/ c^2).

Visual representations of the acceptance mappings, demonstrating negligible target-dependent geometric variance between LH₂ and LD₂, are provided in section 11.

¹¹<https://seaquest-docdb.fnal.gov/cgi-bin/sso/ShowDocument?docid=8588>

¹²<https://seaquest-docdb.fnal.gov/cgi-bin/sso/ShowDocument?docid=11227>

4 Reconstruction Efficiency Correction

The algorithmic efficiency of the kTracker spatial reconstruction package degrades under the high hit-multiplicity characteristic of the primary beam. To accurately quantify this effect without fragmenting our statistical confidence across narrow kinematic intervals, we derive the primary efficiency metric (ϵ_{reco}) by comparing "messy" data overlays against idealized "clean" MC tracks.

Following the verification in DocDB 11427¹³ that ϵ_{reco} decouples from the track kinematics, we extract a high-fidelity **global reconstruction efficiency curve** parameterized explicitly against the Drift Chamber 1 ($D1$) hit array, as demonstrated in fig. 2.

Figure 2: Global Reconstruction Efficiency curve as a function of the $D1$ occupancy variable, integrated over all kinematic bins.

The discrete efficiency weight for any given physical dimuon is mapped dynamically via linear interpolation adjacent to the MC-derived curve edges ($D1^+$, $D1^-$):

$$\epsilon_i = \epsilon(D1^-) + \left(\frac{\epsilon(D1^+) - \epsilon(D1^-)}{D1^+ - D1^-} \right) (D1^+ - D1_i) \quad (7)$$

For combinatorial **mixed events**, the synthetic occupancy is generalized to the arithmetic mean of the parent tracks:

$$D1_{\text{mixed}} = \frac{D1_{\text{pos}} + D1_{\text{neg}}}{2} \quad (8)$$

4.1 Uncertainty Propagation

Maintaining systematic rigor requires precise propagation of the MC interpolation variance. For a singular data event i , the constituent error scales as:

$$\delta\epsilon_i = \frac{1}{D1^+ - D1^-} \sqrt{(D1^+ - D1_i)^2 \delta\epsilon(D1^+)^2 + (D1^- - D1_i)^2 \delta\epsilon(D1^-)^2} \quad (9)$$

¹³<https://sequest-docdb.fnal.gov/cgi-bin/ss0/ShowDocument?docid=11427>

503 The scalar efficiency $\langle\epsilon\rangle$ for an N -event bin emerges as the simple mean (eq. (10)), and the
 504 aggregated statistical uncertainty ($\delta_{\text{prop}}\langle\epsilon\rangle$) propagates quadratically (eq. (11)):

$$\langle\epsilon\rangle = \frac{1}{N} \sum_{i=1}^N \epsilon_i \quad (10)$$

$$\delta_{\text{prop}}\langle\epsilon\rangle = \frac{1}{N} \sqrt{\sum_{i=1}^N (\delta\epsilon_i)^2} \quad (11)$$

505 We generate 2D bin-by-bin topological maps of these corrected efficiencies for both prompt
 506 and mixed events, presented in fig. 3. Covariance matrix inclusion is pending for a future
 507 iteration of this calculation matrix (per DocDB 11431¹⁴).

5 Hodoscope Efficiency Correction

To modernize the historical application of a rigid 0.845 ± 0.125 correction factor (DocDB 10809¹⁵), we have developed an event-by-event dynamic hodoscope resolution metric. Using the extrapolated position vectors at tracking stations 1 and 3, we define the trigger Road ID for every reconstructed dimuon leg. Intersecting these IDs with the dedicated single-track paddle efficiency matrices provided in DocDB 11467¹⁶, we enforce a granular efficiency map (visualized in fig. 4).

Figure 6: Average Hodoscope Efficiencies calculated each kinematic bin with the propagated uncertainties.

6 Total Efficiency Correction

The total analytical efficiency scalar $\epsilon_{\text{total}}^i$ per spatial bin is realized sequentially via the tensor product of the reconstruction and hodoscope efficiencies (eq. (3), aligned with DocDB 11448¹⁷). The resulting kinematics mappings, overlaid with propagated statistical error envelopes, trace the detector's survival probability gradient as presented in fig. 7.

¹⁷<https://sequest-docdb.fnal.gov/cgi-bin/sso/ShowDocument?docid=11448>

Figure 7: Average total Efficiencies calculated each kinematic bin with the propagated uncertainties.

7 Determination of Corrected Yields

Isolating the pure physical event rate from raw counting metrics requires scaling by the average signal efficiency correction $\langle \epsilon_{\text{signal}} \rangle$, defined analytically in eq. (2). This unfolding extracts the definitive background-suppressed yield for each distinct experimental geometry (see DocDB

527 11448¹⁸):

$$Y_{\text{signal}} = \frac{Y_{\text{total}} - Y_{\text{mix}}}{\langle \epsilon_{\text{signal}} \rangle} \quad (12)$$

528 Pathological boundaries in this relation are bounded explicitly:

- 529 • When $Y_{\text{mix}} = 0$, the array implies null combinatorics, reducing to $\langle \epsilon_{\text{signal}} \rangle = \epsilon_{\text{total}}$.
- 530 • In statistically void phase space ($Y_{\text{total}} = 0$ and $Y_{\text{mix}} = 0$), we enforce $\langle \epsilon_{\text{signal}} \rangle = 0$ alongside
- 531 $Y_{\text{signal}} = 0$.
- 532 • A singularity where $Y_{\text{total}} = Y_{\text{mix}} \neq 0$ is structurally averted, as the empirical physical
- 533 prompt yield Y_{total} uniformly dominates Y_{mix} .

534 The spatially resolved maps of the final corrected yields are detailed in fig. 8.

¹⁸<https://sequest-docdb.fnal.gov/cgi-bin/sso/ShowDocument?docid=11448>

(b) Corrected signal yield for LH2

(c) LD2 average signal efficiency correction

(d) Corrected signal yield for LD2

(e) Flask average signal efficiency correction

(f) Corrected signal yield for Flask

Figure 8: Average signal efficiency $\langle \epsilon_{\text{signal}} \rangle$ (left panels) and final corrected signal yields (right panels).

535 The definitive LH₂ corrected yield arises mathematically following the dual subtraction of
 536 uncorrelated mixed pairs and integrated upstream flask background interactions:

$$Y_{\text{corrected}}^{\text{LH}_2} = \frac{Y_{\text{total}}^{\text{LH}_2} - Y_{\text{mixed}}^{\text{LH}_2}}{\langle \epsilon_{\text{signal}}^{\text{LH}_2} \rangle} - \frac{I_{\text{LH}_2}}{I_{\text{flask}}} \left(\frac{Y_{\text{total}}^{\text{flask}} - Y_{\text{mixed}}^{\text{flask}}}{\langle \epsilon_{\text{signal}}^{\text{flask}} \rangle} \right) \quad (13)$$

537 The analogous LD₂ formalism incorporates the supplementary protium isotopic compensation:

$$Y_{\text{corrected}}^{\text{LD}_2} = \frac{Y_{\text{total}}^{\text{LD}_2} - Y_{\text{mixed}}^{\text{LD}_2}}{\langle \epsilon_{\text{signal}}^{\text{LD}_2} \rangle} - \frac{I_{\text{LD}_2}}{I_{\text{flask}}} \left(\frac{Y_{\text{total}}^{\text{flask}} - Y_{\text{mixed}}^{\text{flask}}}{\langle \epsilon_{\text{signal}}^{\text{flask}} \rangle} \right) - \frac{T_{HD}}{T_{HH}} \frac{I_{\text{LD}_2}}{I_{\text{LH}_2}} \left[\frac{Y_{\text{total}}^{\text{LH}_2} - Y_{\text{mixed}}^{\text{LH}_2}}{\langle \epsilon_{\text{signal}}^{\text{LH}_2} \rangle} - \frac{I_{\text{LH}_2}}{I_{\text{flask}}} \left(\frac{Y_{\text{total}}^{\text{flask}} - Y_{\text{mixed}}^{\text{flask}}}{\langle \epsilon_{\text{signal}}^{\text{flask}} \rangle} \right) \right] \quad (14)$$

538 The phase space evolution of these isolated signals is captured in fig. 9.

Figure 9: Corrected yields for LH2 (a) and LD2 (b) after correcting for efficiencies, with propagated uncertainties.

8 Uncertainty Calculation

We bifurcate the error estimation into stochastic bounds and systematic limits. Utilizing standard partial derivative formalisms over the basis vector established in eq. (13), the variance propagates through the measurement topology.

Statistical Uncertainty Components

Because counting variance dominates sparse bin peripheries, the partial derivatives coupling to raw counts take the form:

$$\frac{\partial Y_{\text{corrected}}}{\partial Y_{\text{total}}^{\text{LH2}}} = \frac{1}{\langle \epsilon_{\text{signal}}^{\text{LH2}} \rangle} \quad (15)$$

$$\frac{\partial Y_{\text{corrected}}}{\partial Y_{\text{mixed}}^{\text{LH2}}} = -\frac{1}{\langle \epsilon_{\text{signal}}^{\text{LH2}} \rangle} \quad (16)$$

$$\frac{\partial Y_{\text{corrected}}}{\partial Y_{\text{total}}^{\text{flask}}} = -\frac{I_{\text{LH2}}}{I_{\text{flask}}} \frac{1}{\langle \epsilon_{\text{signal}}^{\text{flask}} \rangle} \quad (17)$$

$$\frac{\partial Y_{\text{corrected}}}{\partial Y_{\text{mixed}}^{\text{flask}}} = \frac{I_{\text{LH2}}}{I_{\text{flask}}} \frac{1}{\langle \epsilon_{\text{signal}}^{\text{flask}} \rangle} \quad (18)$$

Systematic Uncertainty Components from Efficiencies

The covariance of the synthetic signal efficiencies introduces foundational systematic boundaries:

$$\frac{\partial Y_{\text{corrected}}}{\partial \langle \epsilon_{\text{signal}}^{\text{LH2}} \rangle} = -\frac{Y_{\text{total}}^{\text{LH2}} - Y_{\text{mixed}}^{\text{LH2}}}{\langle \epsilon_{\text{signal}}^{\text{LH2}} \rangle^2} \quad (19)$$

$$\frac{\partial Y_{\text{corrected}}}{\partial \langle \epsilon_{\text{signal}}^{\text{flask}} \rangle} = \frac{I_{\text{LH2}}}{I_{\text{flask}}} \frac{Y_{\text{total}}^{\text{flask}} - Y_{\text{mixed}}^{\text{flask}}}{\langle \epsilon_{\text{signal}}^{\text{flask}} \rangle^2} \quad (20)$$

Uncertainty Propagation

Assuming ideal Poissonian variance over the constituent arrays ($\sigma_Y^2 \approx Y$), the absolute statistical error bounds map natively via quadrature addition:

$$\delta Y_{\text{corrected}}^{\text{stat}} = \left[\left(\frac{\partial Y_{\text{corrected}}}{\partial Y_{\text{total}}^{\text{LH2}}} \right)^2 Y_{\text{total}}^{\text{LH2}} + \left(\frac{\partial Y_{\text{corrected}}}{\partial Y_{\text{mixed}}^{\text{LH2}}} \right)^2 Y_{\text{mixed}}^{\text{LH2}} + \left(\frac{\partial Y_{\text{corrected}}}{\partial Y_{\text{total}}^{\text{flask}}} \right)^2 Y_{\text{total}}^{\text{flask}} + \left(\frac{\partial Y_{\text{corrected}}}{\partial Y_{\text{mixed}}^{\text{flask}}} \right)^2 Y_{\text{mixed}}^{\text{flask}} \right]^{1/2} \quad (21)$$

By construction, the fractional statistical dispersion holds equivalently across the integrated cross section:

$$\frac{\delta \sigma^{\text{stat}}}{\sigma} = \frac{\delta Y_{\text{corrected}}^{\text{stat}}}{Y_{\text{corrected}}} \quad (22)$$

The macroscopic systematic limit, isolated to detector and spatial correction drift, evolves

554 from the efficiency deviations via:

$$\delta Y_{\text{corrected}}^{\text{sys,eff}} = \left[\left(\frac{\partial Y_{\text{corrected}}}{\partial \langle \epsilon_{\text{signal}}^{\text{LH2}} \rangle} \delta \langle \epsilon_{\text{signal}}^{\text{LH2}} \rangle \right)^2 + \left(\frac{\partial Y_{\text{corrected}}}{\partial \langle \epsilon_{\text{signal}}^{\text{flask}} \rangle} \delta \langle \epsilon_{\text{signal}}^{\text{flask}} \rangle \right)^2 \right]^{1/2} \quad (23)$$

555 The ultimate systematic constraint $\delta \sigma^{\text{syst.}}$ represents the integration of three primary per-
556 turbations:

- 557 • Monte Carlo spatial acceptance mappings ($\mathcal{A}$) [section 3]
- 558 • Detector and analytical correction yield deviations ($Y_{\text{corrected}}$) [Detailed above]
- 559 • Invariant mass contamination via the ψ' radiative tail ($Y_{\psi'}/Y_{DY}$) [section 14]

560 Evaluating these linearly against the macroscopic continuum yield resolves the absolute error
561 fields:

$$\delta \sigma_{\text{acc}}^{\text{syst.}} = \left(\frac{\delta \mathcal{A}}{\mathcal{A}} \right) \sigma \quad (24)$$

$$\delta \sigma_{\text{yield}}^{\text{syst.}} = \left(\frac{\delta Y_{\text{corrected}}^{\text{sys,eff}}}{Y_{\text{corrected}}} \right) \sigma \quad (25)$$

$$\delta \sigma_{\psi'}^{\text{syst.}} = (Y_{\psi'}/Y_{DY}) \times \sigma \quad (26)$$

562 To preserve structural coherence, the non-correlated topological components combine into
563 the aggregate bound via Cartesian sum:

$$\delta \sigma^{\text{syst.}} = \sqrt{\left(\delta \sigma_{\text{acc}}^{\text{syst.}} \right)^2 + \left(\delta \sigma_{\text{yield}}^{\text{syst.}} \right)^2 + \left(\delta \sigma_{\psi'}^{\text{syst.}} \right)^2} \quad (27)$$

564 *(Note: Error translation into the LD₂ framework follows a parallel methodology modified
565 structurally to accommodate the scalar variance of the internal isotopic subtraction).*

9 Cross-Section Results

9.1 LH2 Results (Reported at mass bin average)

We define the primary measurement space plotting the absolute double-differential cross-section of the LH_2 dataset aligned with the internal mass centroid of each kinematic grid. These values are plotted alongside Next-to-Leading-Order calculations using the CT18 and NNPDF4.0 parameterizations to evaluate theoretical consistency.

Statistical voids present in boundary grids currently induce elevated uncertainty spans, which will resolve following the planned merging of adjacent roadsets.

10 Appendix: Event Selection Criteria (Chuck Cuts)

This standardized matrix parameterizes the specific topological limits applied to suppress upstream background interactions, cosmics, and combinatoric tracking vectors inside the spectrometer logic.

In the subsequent tables, the y -axis displacement generated by the beam geometry defines the intrinsic offset $y_{\text{beam}} = 1.6$ cm.

10.1 Single Track Cuts

These discrete geometric and analytic bounds govern individual constituent muon trajectories.

Table 1: Single track selection criteria.

Variable	Condition
Track Fit Quality	
Target χ^2	$\chi_{\text{target}}^2 < 15$
Reduced χ^2	$\chi^2 / (N_{\text{hits}} - 5) < 12$
Vertex Assumption	$\chi_{\text{target}}^2 < 1.5 \times \chi_{\text{dump}}^2$ AND $\chi_{\text{target}}^2 < 1.5 \times \chi_{\text{upstream}}^2$
Hits & Geometry	
Number of Hits	$N_{\text{hits}} > 13$
Station 1 Z-Momentum	$9 < p_{z,\text{st1}} < 75$ GeV/ c
Single Track Vertex z	$-320 < z_v < -5$ cm
Aperture & Trajectory	
Radial pos. at target ($z \approx -130$ cm)	$x^2 + (y - y_{\text{beam}})^2 < 320$ cm ²
Radial pos. at dump ($z \approx 50$ cm)	$16 < x^2 + (y - y_{\text{beam}})^2 < 1100$ cm ²
Vertical Focusing	$y_{\text{st1}} / y_{\text{st3}} < 1$
Vertical Projection	$y_{\text{st1}} \cdot y_{\text{st3}} > 0$
Min Vertical Momentum	$ p_{y,\text{st1}} > 0.02$ GeV/ c
Momentum Conservation	
KMag Momentum Kick	$ p_{x,\text{st1}} - p_{x,\text{st3}} - 0.416 < 0.008$ GeV/ c
Vertical Bend (Null)	$ p_{y,\text{st1}} - p_{y,\text{st3}} < 0.008$ GeV/ c
Longitudinal (Null)	$ p_{z,\text{st1}} - p_{z,\text{st3}} < 0.08$ GeV/ c

10.2 Dimuon Cuts

This secondary matrix verifies the topological fidelity of the merged pairs relative to the experimental fiducial volume.

10.3 Occupancy and Topology Cuts

This boundary matrix isolates standard physics triggers explicitly from high-density combinatorial noise loops within the kTracker routine.

Table 2: Dimuon kinematic and vertex selection criteria.

Variable	Condition
Vertex Position	
Transverse Offset (x)	$ dx < 0.25$ cm
Vertical Offset (y)	$ dy - y_{\text{beam}} < 0.22$ cm
Radial Vertex	$dx^2 + (dy - y_{\text{beam}})^2 < 0.06$ cm ²
Longitudinal Vertex (z)	$-280 < dz < -5$ cm
Vertex Fit Quality	$\chi_{\text{dimuon}}^2 < 18$
Vertex Consistency	$ \chi_{\text{trk1}}^2 + \chi_{\text{trk2}}^2 - \chi_{\text{dimuon}}^2 < 2$
Kinematics	
Invariant Mass	$4.2 < M_{\mu\mu} < 8.8$ GeV/ c^2
Feynman- x	$-0.1 < x_F < 0.95$
Transverse Scaling x_T	$0.05 < x_T \leq 0.58$
Costh (Collins-Soper)	$ \cos \theta < 0.5$
Longitudinal Momentum	$38 < p_z < 116$ GeV/ c
Transverse Momentum limits	$ dp_x < 1.8$ GeV/ c , $ dp_y < 2.0$ GeV/ c
Total p_T	$dp_x^2 + dp_y^2 < 5.0$ (GeV/ c) ²
Track Separation	$\text{sep} < 270$ cm

Table 3: Occupancy and topological cuts.

Variable	Condition
Chamber Occupancy	
Drift Chamber 1 Hits	$D1 < 400$
Drift Chamber 2 Hits	$D2 < 400$
Drift Chamber 3 Hits	$D3 < 400$
Total Chamber Hits	$D1 + D2 + D3 < 1000$
Topology	
Opposite Quadrants	$y_{\text{st3}}^{\text{trk1}} \cdot y_{\text{st3}}^{\text{trk2}} < 0$
Total Hits on Tracks	$N_{\text{hits}}^{\text{trk1}} + N_{\text{hits}}^{\text{trk2}} > 29$
Station 1 Hits Sum	$N_{\text{hits, st1}}^{\text{trk1}} + N_{\text{hits, st1}}^{\text{trk2}} > 8$
Station 1 X-Sum	$ x_{\text{st1}}^{\text{trk1}} + x_{\text{st1}}^{\text{trk2}} < 42$ cm

14 Appendix: ψ' Contamination Study

To quantify the systematic uncertainty arising from the ψ' resonance contamination within our signal region, we evaluated the background contribution across the invariant mass spectrum. Specifically, for each defined mass bin, this systematic uncertainty was determined by evaluating the ratio of the extracted ψ' yield to the Drell-Yan (DY) yield ($Y_{\psi'}/Y_{DY}$). The statistical and fit uncertainties from the individual yield extractions were rigorously propagated to calculate the total propagated uncertainty for each mass bin, which is visually represented in the $Y_{\psi'}/Y_{DY}$ ratio plot. The following figures illustrate the Monte Carlo (MC) fit plots utilized to model these shapes and extract the respective yields across the mass bins. The study was explained in docdb 11454.

Figure 68: Plots of ψ' contamination generated by using MC with the ratio $Y_{\psi'}/Y_{DY}$

(a) $0.0 \leq x_F < 0.05$

(b) $0.05 \leq x_F < 0.1$

(c) $0.1 \leq x_F < 0.15$

(d) $0.15 \leq x_F < 0.2$

Figure 69: Plots of ψ' contamination generated by using MC with the ratio $Y_{\psi'}/Y_{DY}$

(a) $0.2 \leq x_F < 0.25$

(b) $0.25 \leq x_F < 0.3$

(c) $0.3 \leq x_F < 0.35$

(d) $0.35 \leq x_F < 0.4$

Figure 70: Plots of ψ' contamination generated by using MC with the ratio $Y_{\psi'}/Y_{DY}$

(a) $0.4 \leq x_F < 0.45$

(b) $0.45 \leq x_F < 0.5$

(c) $0.5 \leq x_F < 0.55$

(d) $0.55 \leq x_F < 0.6$

Figure 71: Plots of ψ' contamination generated by using MC with the ratio $Y_{\psi'}/Y_{DY}$

(a) $0.6 \leq x_F < 0.65$

(b) $0.65 \leq x_F < 0.7$

(c) $0.7 \leq x_F < 0.75$

(d) $0.75 \leq x_F < 0.8$

15 Appendix: Determination of Mass Bin Centroids

In order to accurately plot the double-differential cross-sections, the horizontal placement of the data points must reflect the true physical average of the invariant mass within each finite mass bin, rather than the simple geometric center. Because the dimuon mass distribution falls exponentially, the true centroid is typically skewed toward the lower edge of the bin.

To account for combinatoric backgrounds, efficiency corrections, and flask contributions, the centroid calculation must be weighted using the fully corrected equations for the yields.

For the LH₂ target, the corrected yield is given by:

$$Y_{\text{corrected}}^{\text{LH}_2} = \frac{Y_{\text{total}}^{\text{LH}_2} - Y_{\text{mixed}}^{\text{LH}_2}}{\langle \epsilon_{\text{signal}}^{\text{LH}_2} \rangle} - \frac{I_{\text{LH}_2}}{I_{\text{flask}}} \left(\frac{Y_{\text{total}}^{\text{flask}} - Y_{\text{mixed}}^{\text{flask}}}{\langle \epsilon_{\text{signal}}^{\text{flask}} \rangle} \right) \quad (28)$$

For the LD₂ target, the corrected yield accounts for both the empty flask and the hydrogen contribution:

$$Y_{\text{corrected}}^{\text{LD}_2} = \frac{Y_{\text{total}}^{\text{LD}_2} - Y_{\text{mixed}}^{\text{LD}_2}}{\langle \epsilon_{\text{signal}}^{\text{LD}_2} \rangle} - \frac{I_{\text{LD}_2}}{I_{\text{flask}}} \left(\frac{Y_{\text{total}}^{\text{flask}} - Y_{\text{mixed}}^{\text{flask}}}{\langle \epsilon_{\text{signal}}^{\text{flask}} \rangle} \right) - \frac{T_{\text{HD}}}{T_{\text{HH}}} \frac{I_{\text{LD}_2}}{I_{\text{LH}_2}} \left[\frac{Y_{\text{total}}^{\text{LH}_2} - Y_{\text{mixed}}^{\text{LH}_2}}{\langle \epsilon_{\text{signal}}^{\text{LH}_2} \rangle} - \frac{I_{\text{LH}_2}}{I_{\text{flask}}} \left(\frac{Y_{\text{total}}^{\text{flask}} - Y_{\text{mixed}}^{\text{flask}}}{\langle \epsilon_{\text{signal}}^{\text{flask}} \rangle} \right) \right] \quad (29)$$

The mass bin centroid for the LH₂ target is then calculated as the efficiency-corrected, background-subtracted mass sum divided by the corrected yield:

$$\langle M \rangle_{\text{LH}_2} = \frac{1}{Y_{\text{corrected}}^{\text{LH}_2}} \left[\frac{\sum M_{\text{total}}^{\text{LH}_2} - \sum M_{\text{mixed}}^{\text{LH}_2}}{\langle \epsilon_{\text{signal}}^{\text{LH}_2} \rangle} - \frac{I_{\text{LH}_2}}{I_{\text{flask}}} \left(\frac{\sum M_{\text{total}}^{\text{flask}} - \sum M_{\text{mixed}}^{\text{flask}}}{\langle \epsilon_{\text{signal}}^{\text{flask}} \rangle} \right) \right] \quad (30)$$

Similarly, we calculate the mass bin centroid for the LD₂ target using the fully corrected yield and mass sums:

$$\langle M \rangle_{\text{LD}_2} = \frac{1}{Y_{\text{corrected}}^{\text{LD}_2}} \left\{ \frac{\sum M_{\text{total}}^{\text{LD}_2} - \sum M_{\text{mixed}}^{\text{LD}_2}}{\langle \epsilon_{\text{signal}}^{\text{LD}_2} \rangle} - \frac{I_{\text{LD}_2}}{I_{\text{flask}}} \left(\frac{\sum M_{\text{total}}^{\text{flask}} - \sum M_{\text{mixed}}^{\text{flask}}}{\langle \epsilon_{\text{signal}}^{\text{flask}} \rangle} \right) - \frac{T_{\text{HD}}}{T_{\text{HH}}} \frac{I_{\text{LD}_2}}{I_{\text{LH}_2}} \left[\frac{\sum M_{\text{total}}^{\text{LH}_2} - \sum M_{\text{mixed}}^{\text{LH}_2}}{\langle \epsilon_{\text{signal}}^{\text{LH}_2} \rangle} - \frac{I_{\text{LH}_2}}{I_{\text{flask}}} \left(\frac{\sum M_{\text{total}}^{\text{flask}} - \sum M_{\text{mixed}}^{\text{flask}}}{\langle \epsilon_{\text{signal}}^{\text{flask}} \rangle} \right) \right] \right\} \quad (31)$$

Here, we plot dimuon yield distributions for LH₂ cross-section calculations for the following components:

- LH₂ total (red)
- LH₂ mixed (blue)
- Flask total (green)
- Flask mixed (orange)

Then, the table of each dimuon component, efficiency corrections, and resulting mass bin centroids are presented for each x_F bin. Similarly, for LD₂ cross-section calculations, we plot the following components:

- LD₂ total (red)
- LD₂ mixed (blue)

645 • Flask total (green)

646 • Flask mixed (orange)

647 These represent the total, mixed background, and flask components used in these calcula-
648 tions. Alongside the distributions are the precise kinematic values, raw counts, and resulting
649 mass bin centroids for each x_F bin. Finally, the table of each dimuon component, efficiency
650 corrections, and resulting mass bin centroids are presented for each x_F bin for the LD₂ target
651 as well. This detailed breakdown allows for a clear understanding of how the final cross-section
652 points are derived from the raw data and corrections.

653 **15.1 Mass bin centroid calculations in $x_F \in [0.00, 0.05)$**

Figure 72: Invariant Mass distributions for LH₂ in the range $x_F \in [0.00, 0.05)$. Components shown include target total (red), target mix (blue), flask total (green), and flask mix (orange). The values listed above each bin represent the efficiency-weighted corrected mass $\sum M/\epsilon$ and the raw counts (N).

15.6 Mass bin centroid calculations in $x_F \in [0.25, 0.30)$

Figure 82: Invariant Mass distributions for LH₂ in the range $x_F \in [0.25, 0.30)$. Components shown include target total (red), target mix (blue), flask total (green), and flask mix (orange). The values listed above each bin represent the efficiency-weighted corrected mass $\sum M/\epsilon$ and the raw counts (N).

Table 19: LH₂ raw counts, efficiency corrections, yields, and final data-driven centroids for $x_F \in [0.25, 0.30)$.

668 **15.16 Mass bin centroid calculations in $x_F \in [0.75, 0.80)$**

Figure 102: Invariant Mass distributions for LH₂ in the range $x_F \in [0.75, 0.80)$. Components shown include target total (red), target mix (blue), flask total (green), and flask mix (orange). The values listed above each bin represent the efficiency-weighted corrected mass $\sum M/\epsilon$ and the raw counts (N).

Table 39: LH₂ raw counts, efficiency corrections, yields, and final data-driven centroids for $x_F \in [0.75, 0.80)$.

Mass Bin (GeV)	Geo. $\langle M \rangle$	$\langle M \rangle$ (LH ₂)	$N_{\text{tot}}^{\text{LH}_2}$	$N_{\text{mix}}^{\text{LH}_2}$	$N_{\text{tot}}^{\text{fl}}$	$N_{\text{mix}}^{\text{fl}}$	$\langle \epsilon_{\text{sig.}}^{\text{LH}_2} \rangle$	$\langle \epsilon_{\text{sig.}}^{\text{LD}_2} \rangle$	$\langle \epsilon_{\text{sig.}}^{\text{fl}} \rangle$	$\sum M_{\text{corr}}^{\text{LH}_2}$ (Num.)	$Y_{\text{corr}}^{\text{LH}_2}$ (Denom.)
